Eye and head movements

DYNAMIC MULLER-LYER ILLUSION

The red dots are equidistant, though the extremities of the line seem to alternately stretch and shrink like a rubber band.

Tracking

Types	Description	Comments
Nystagmus	small, rapid, oscillatory	keep things visible
Saccades	ballistic, fast	spatial frame of ref
(Smooth) Pursuit	track moving target	speed dependent
Vergence	Con/Diverge; disconjugate	cue to depth
Vestibular Ocular Response (VOR)	Stabilize eyes in head	stabilize in 3D
Optokinetic	stabilize moving field	size of motion field critical
Accommodation	Change in shape of lens	focus
Pupillary response	Change in lighting	

EYE MOVEMENTS that are halted in stabilized vision normally carry an image across the receptors of the retina as shown here. The three movements are a drift (*curved lines*) away from the center of vision, a faster flick (*straight lines*) back toward the center and a high-frequency tremor superimposed on the drift. The magnitude of all these movements is very small; the diameter of the patch of the fovea shown above is only .05 millimeter.

Image paths on the retina

STABILIZED IMAGES typically fade as in the illustrations on this and the following two pages. The parts of a profile drawing that stay visible are invariably specific features or groups of features, such as the front of the face or the top of the head.

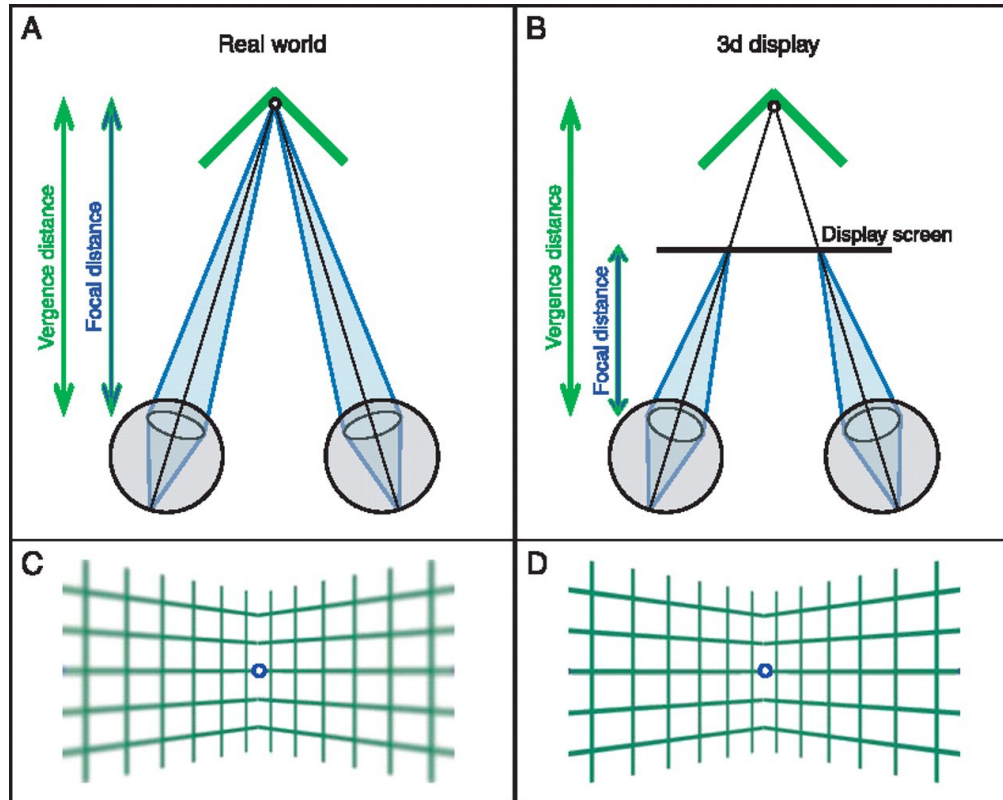

MEANINGLESS CURLICUES first come and go in random sequence. But after a while small groups of curlicues organized in recognizable patterns start to behave as units. This suggests that they have themselves become meaningful perceptual elements.

Image stabilization results in perceptual fading
(Pritchard, 1961)

Vergence

Vergence/accommodation conflict complicates **virtual reality (VR) displays**

Smooth pursuit

**Vestibulo Ocular Reflex/Response (VOR) stabilizes
gaze**

Demo: VOR permits reading/texting while walking
